Abstract

The exodus of Soviet Jews to Israel in the 1990s was a unique event. The immigration wave was distinctive for its large high skilled cohort, its quick integration into the domestic labor market, and its unprecedented election participation rate. The Immigration wave changed the entire economic landscape: it raised productivity, underpinned by the information technological surge, and had significant impact on income inequality. The extraordinary experience of Israel, which has received three quarter million migrants from the Former Soviet Union within a short time, is also relevant for the current debate about winners and losers from immigration. This paper provides evidence and a rigorous political-economy explanation for a potential link between the immigration wave and the marked changed level of redistribution in Israel's welfare state.

1. Introduction

Globalization is currently facing some challenging political tests, more than in past decades.

¹ I wish to acknowledge useful comments from Gordon Hanson and the referee.

Migration is the core of the emerging economic nationalism, which threatens to tear off international integration developments. Jeff Sachs (2017) puts it succinctly when he says: “If people were told that they could move, no questions asked, probably a billion would shift around the planet within five years, with many coming to Europe and the US. No society would tolerate even a fraction of that flow. Any politician who says, ‘let’s be generous,’ without saying ‘we’re not going to let the doors stand wide open’ will lose.” The core of the wall-building coalition in the United States consists of white males with low educational attainment. Low-income citizens were also far more likely to support Brexit in the United Kingdom. Evidently, rational and generous policy that also resonates politically will not eliminate national borders altogether. Rather, immigration policy may elicit economic-social based arguments for limits on the flow of migrants. The argument for a “points-based” immigration system is an explicit call to increase the skill composition of UK immigrants. However, because there are no barriers put on Israel by the Law of Return, Israel not only enables free immigration but also grants returnees immediate citizenship, regardless of origin and skill. For an economist, it is like a laboratory experiment of how free migration can function without noneconomic forces and anti-migration sentiments which drive barriers for immigration.

Over the long history, demographic trends often shift the balance of politics among ethnic groups, economic classes and age groups. However, the assimilation of immigrants in the electoral system in Israel has been relatively robust; and ,therefore, the change in the political balance was substantial. Recall that Israel’s Law of Return grants returnees immediate citizenship and consequently voting rights.² An early study by Avner (1975) finds that the voting turnout rate of new immigrants was markedly lower than that of the established population. This

²

means that immigrants did not fully exercise their voting rights and did not therefore influence the political economy equilibrium in Israel as much as the established population. However, a later study conducted by Arian and Shamir (2002) about voting turnout patterns of new immigrants to Israel in the 2001 elections reverses the earlier finding, the new immigrants in this study are predominantly from the Former Soviet Union (FSU). Arian and Shamir find no marked difference in voting turnout rates between the new immigrants and the established population. Immigrants' voting is key to understanding the political-economy mechanism that determines income distribution and redistribution (see Razin, Sadka and Swagel (2002 a, b).

Generally speaking, migration differs from the movement of other factor inputs (such as capital flows) in one fundamental way. Migrants become part of the society of the receiving country, including its evolving culture and politics.³ A highly developed social welfare system in the receiving country may greatly complicate matters, as emphasized by Razin, Sadka and Swagel (2002b). A related issue is the implications of ageing population for the size of the welfare state; see Razin, Sadka, and Suwankiri (2011). While high skilled and therefore high-wage migrants may be net contributors to the fiscal system, low skilled migrants are likely to be net recipients, thereby imposing an indirect tax on the taxpayer of the receiving country. Sooner or later, then, migrants may shift the balance of politics among ethnic groups, economic classes, or age groups, and reshape the distribution of wealth and disposable income, That is, immigrants influence the size of the welfare state directly through the electoral system, and indirectly, through their effect on market based inequality.

³ The Swiss playwright Max Frisch put it dramatically: "We asked for workers. We got people".

The organization of the paper is as follows. Section 2, provides a background to Israel's unique immigration story. Section 3 discusses migrant's high-skill characteristics. Section 4 addresses the unique assimilation story of the immigrants from the Former Soviet Union. Section 5 develop a political economic theory to shed light on the inequality consequences of the immigration from the Former Soviet Union. Section 6 concludes.

2. Historical Background

Immigration has far-reaching economic and social consequences. These include the labor market, international trade, economic growth, the social and political structure, etc. (see, e.g., Lucas (2014) for a recent treatise), as has long been known. Between 1990 and 2012, almost 20m people moved from Central, Eastern and South-Eastern Europe to richer countries in Western Europe, about 8 percent of the population of Europe. This east-west migration accelerated after 2004 when eight eastern European countries, including Poland, the Czech Republic and Hungary, joined the EU. At the same time, Israel received almost 1m immigrants, about 20 percent of Israel's population. In both episodes migration borders restrictions were eased. Both in the Israeli case and within the EU's borders is the free movement of people tied to the free movement of trade and capital. However, key differences between the two episodes, in addition to the relative size of the flow of migrants, are in the skill levels of the immigrants and the migrant-absorption policies that the receiving countries embraced.

The unique experience of Israel is vastly different for continuing of the globalization effort, not only from the recent experience in Europe, but also from the US experience. The core of the "wall-building" coalition in the US is white males with low educational attainment. Low income British

were far more likely to support Brexit in the UK. The call for a “points based” immigration system from the Brexit campaign was an explicit call to increase the skill composition of UK immigrants. How does one explain the recent anti-immigration sentiment by a simple argument based on first principles? Low-skilled immigrants compete for low skill native-born jobs, and depress their wages. Furthermore, low-skilled immigrants are also more likely to be net beneficiaries from the typically generous welfare state- the burden of which low-skilled workers share. In contrast, high-skill immigrants may increase the productivity of the low-skilled population and are net fiscal contributors, making them a more attractive form of immigration. Low-skill segment of the destination-country established population. Therefore, net fiscal burden underpins the discontents with immigration. It would tilt the composition of immigration toward high-skilled workers. Other groups are more likely to gain from low-skilled immigration. They increase the wages of high-skill workers and do not necessarily impose a fiscal burden on retirees, who no longer fund the welfare state. Therefore high skill workers support the globalization course that advanced economies have taken until the more recent wave of anti-immigration sentiment. In Israel, as we will see, the political-economy major effect of the 1990s-early 2000s migration wave is on income inequality through the downsizing of the welfare state. However, partly because of the successful integration, no significant anti-migration sentiments emerged.

The exodus of Soviet Jews to Israel in the 1990s, especially its impacts on income inequality and the political balance of power vivifies Lucas’s findings.⁴ Israel is well known for the unique ways it absorbs immigrants; who in turn tend to arrive in waves triggered by external shocks. Each wave has its unique

⁴ Benhabib and Jovanovich (2012) consider world-welfare perspective. My analysis focuses on an individual state. See also Razin (2018) for the various ways that Israel benefitted from being a part of the post-World War II globalization wave, with capital, finance, and goods mobility at its core.

origin, distribution of skills, and often socio-economic characteristics. Thus, the exodus of Soviet Jews in the 1990s adds useful insights into this ongoing experiment.

The importance of the Soviet Jewish exodus is best appreciated when one thinks in historical perspective. Immigration to the pre-state Palestine and to the state of Israel came in waves from the late 19th century onwards.⁵ During the pre-state era (prior to 1948), immigration was at times controlled by the British rulers.⁶ However, immigration was free, and even encouraged, under the umbrella of the “Law of Return”. Table 2.1 suggests that immigration at times, especially in the nascent statehood and in the last wave from the Former Soviet Union (FSU) constitutes about 20% of the established population.

Table 1: Immigration, 1922-2001

Period	Immigrants as a Percentage of Established Population	Annual Percentage Growth Rate of Population
1922-32	8.2	8.0
1932-47	6.4	8.4
1947-50	19.8	21.9
1950-51	13.2	20.0
1951-64	2.2	4.0
1964-72	1.3	3.0
1972-82	0.9	2.1
1982-89	0.4	1.8
1989-2001	19.0	-

⁵ See Razin and Sadka (1993).

⁶ After World War I the League of Nations granted Great Britain a mandate over the whole of Palestine. It ended in May 1948, when Israel gained its independence.

Soviet-Jew immigration of the 1990s stands out from previous waves both because of its sheer volume and because the economic motivation. The choice, albeit limited by immigration restrictions of the advanced countries in the West: Australia, Canada, Germany, was between Israel and the rest, and US. In fact for a portion of would be immigrants, Israel was a second- choice.

The disunion of the Soviet Union and the destruction of communism in the USSR 1987-1991 triggered the recent wave of Soviet Jews (Figure 1) to various parts of the world, including Israel.

Figure 1: Emigration of Jews and their family members from the former USSR to Israel, USA and Germany (left axis, thousands) and the fraction of Jews in Israel (right axis, percent)

Source: <http://demoscope.ru/weekly/2012/0497/demoscope497.pdf>

All the migrant-destinations are controlled by the migration policies of the receiving countries, except Israel. Immigration into Israel is free by the *Law of Return*.

The primary driver of Jewish exodus from Russia 1990-1996 was the Soviet Union's and subsequently Russia's economic collapse, often-dubbed "katastroika". The Jewish community sensed the pain, anticipated the danger and fled for this compelling reason, but also due to the twin threats of a military *coup d'tat* and civil war. Both the demise of the Soviet Union and the following exodus in a macroeconomic jargon is a supply side shock, which triggers sizeable migration flows. The communist regime inaugurated a liberalization campaign in the political ("demokratizatsiya"), economic ("perestroika"), social and international spheres ("novoe myshlenie") that expanded opportunities of many, including the Soviet Jews to increase their welfare.⁷ However, they were legally barred from leaving the country until the complete demise of the regime. The prospect of brighter tomorrows in more stable and advanced , reinforced by mounting political, social and economic turmoil which raised the risk of civil war, created the specter of a military *coup d'etat*, threatened economic collapse.

The Soviet-Union economy ceased growing in 1989 and then plummeted nearly 10 percent in 1990 as enterprise managers focused on privatizing state assets to themselves ("spontaneous privatization"), liquidating them and transferring balances abroad instead of dedicating them to current operations. Inter-industrial supplies, the backbone of modern economies were shattered because managers ignored their contractual obligations to intermediate input users.

⁷ The first hint came in the enterprise reform law of January 1988, which allowed state enterprise managers to use company funds at their discretion instead of complying strictly with central plans ("tekhpromfinplans"). Soon thereafter, central plans ceased being obligatory. The stated intention of the enterprise reform law was to give managers more latitude in dealing with day-to-day operations, but the opportunity to divert funds from operations and investment to personal consumption and round-a-about insider privatization was not missed ("kleptostroika").

This was shock therapy in action without Sachs’s conditionality.⁸ In theory, Soviet managers who had no experience designing and marketing products to satisfy consumer demand were expected to transform themselves into efficient competitors under duress. However, they could not do it. The reality was an economic depression that caused GDP to fall between 37 and 50 percent between 1989 and 1998.⁹ Full economic recovery has not been achieved until 2006.

The Soviet Union’s crumbling sphere of influence in Central Europe and East Germany, together with the successful secession of the Baltic States alerted the Russian Jewish community to the wisdom of *carpe diem*. A window of opportunity had opened, and Jewish emigres of the 1990s chose to seize the day. Migration waves and growth: bird’s eye

One of the most distinctive features associated with the *Aliyah* waves is the high rates of economic growth.¹⁰ See Table 2.

Table 2: Aliyah and Growth, 1922-2015 (annual percentage growth rates)

Period	<i>Olim</i> as a percentage of established population	Population Growth rate	Capital stock growth rate (excluding housing)	Housing Stock Growth rate	Per capita Output growth rate (not cyclically adjusted)
1922-1931	9.5	8.0	---	---	7.8

⁸ Sachs (2012).

⁹ Rosefielde and Hedlund (2009).

¹⁰ Although the table alludes to simple correlation between migration and growth, the migration-wave shocks are considered to be an exogenous variable; a migration-push factor triggered by forces in the origin country. .See Neuman (1999).

1932-1946	15.6	8.4	---	---	3.0
1947-1949	37.7	21.9	---	---	---
1950-1951	26.1	20.0	---	---	10.0
1952-1963	19.4	4.0	12.8	11.6	4.9
1964-1971	8.3	3.0	8.7	7.7	5.5
1972-1982	7.6	2.1	6.1	7.7	0.8
1983-1989	2.7	1.8	3.1	4.0	3.1
1990-2001	16.5	3.0	7.0	4.7	2.5
2002-2007	1.9	1.8	2.4	2.5	1.9
2008-2015	1.8	2.0	3.4	3.2	1.3

Source: Ben Porath (1985) for the years 1922-82. Central Bureau of Statistics (2016) and Bank of Israel (2016).

Table 2 indicates that the *Aliyah* produced massive investments, both in residential structures and in non-residential capital. These investments were so substantial that they increased the capital to labor ratio and facilitated economic growth. In some cases further aided by the remarkable human capital brought by the *olim*. Except for the *olim* who came during the major wave of *Aliyah* immediately after the birth of the state of Israel, the education level of the *olim* generally exceeded that of the established population and thus contributed remarkably to overall productivity. It is also noteworthy that in general the massive investments in physical capital and infrastructures were financed by capital imports (reflected in persistent current account deficit), as the *olim* themselves

fled their former homes almost penniless and credit constrained so that they hardly saved. Table 2.3 shows, for instance, that during the years 1922-31, when the number of *olim* each year was about 9.5 percent of the established population, output increased at the whopping rate of about 16.4% per annum, so that output per capita increased by a remarkable 7.8 % per annum. Similarly, during the years 1950-51, when the percentage of *olim* each year amounted to about 26.1% of the established population, output increased by about 10% per annum. During the years 1952-63, when the percentage of *olim* each year amounted to about 19.4%, output growth was steady, 4.9 percent *per annum*. In this period, capital stock growth rate was 12.8 % and housing stock by 11.6 percent - a whopping investment boom. In contrast, during the years 1972-82, when the percentage of *olim* each year amounted to about 7.6 output per capita rose by the meager rate of 0.8 % *per annum* (obviously, the oil price shock cum Yom Kippur War depressed output growth). In the later years, output growth was a declining trend the percentage of *olim* each year amounted to 16.5%, output growth was meager 2.5 percent *per annum*.

Obviously, Table 2 is only suggestive for the role played by immigration and the massive investment, which accompanied its big waves, in growing the economy. Evidently, the statistics in Table 2.3 reflect the effects of business cycle fluctuations, external shocks, military conflicts, and the like, in addition to the migration waves.

3. Migrant Characteristics

The professional, social, attitudinal and behavioral characteristics of the 1990s Jewish exodus cohort proved to be distinctive. Immigrants came mostly from urban areas, with advanced education systems. Their skill (education) composition is heavily skewed towards high education

levels; skewness in their relatively higher labor income (see Table 3). Their share in the population was sizable - 14.5%. Their average family size (2.32 standard persons) was lower than the national average (2.64 standard persons). This indicates fewer dependents. Most important was their higher education level and consequently their higher labor income. The average number of schooling years of the new immigrants was 14.0, compared to the national average of only 13.3.

Table 3: The Skill, Age and Income of Immigrants from the FSU and the National Average, 1990-2011

	Immigrants from the FSU	National Average ¹¹
Share in Total Population (%)	14.5	100
Household Size (numbers of standard persons)	2.32	2.74
Schooling Years Of Head of Household (no.)	14	13.3
Head of household with a bachelor degree (%)	41.1	29.5
gross monthly labor income per standard person (2011 NIS)	4,351	4,139

Source: Eilam (2014)

Even more striking was the percentage of heads of the households with bachelor degrees: 41.1% among the new immigrants, compared to a national average of just 29.5%. The higher education level and the lower family size can presumably explain the income gap: the average labor income per standard person of the new immigrants was NIS 4,351, compared to a national average of only

¹¹ Including immigrants.

NIS 4,139. Noteworthy, this gap existed even though the new immigrants had lower work seniority than the established population.

The educational achievement figures of the immigrants from the FSU are impressive compared to the EU-15. Relying on data from the International Organization for Migration (IOM) and the OECD, Razin and Sadka (2014) report that only 18% of the stock of immigrants in the EU-15 in 1990 and 24% in 2000 had tertiary education.

4. Assimilation Story: Catching Up

Cohen and Hsieh (2001) show that average effective wages of native Israelis fell and the return to capital increased during the height of the influx in 1990 and 1991. By 1997 however, both average wages and the return to capital had returned to pre-immigration levels due to an investment boom induced by the initial increase in the return to capital. As predicted by the standard intertemporal model of the current account¹², the investment boom was largely financed by external borrowing. Furthermore, despite the high educational levels of the Russian immigrants, the Russian influx did not lower the skill-premium of native Israelis. They explain this effect by the rise in Total Factor Productivity during the 1990s relative to stunningly low productivity increase through much of the 1970s and 1980s. Eckstein and Weiss (2004) develop a descriptive methodology for the analysis of wage growth of immigrants that is based on human capital theory. The sources of the wage growth are (1) the rise of the return to imported human capital, (2) the impact of accumulated experience in the host country, and (3) the mobility up the occupational ladder in the host country.

¹² See Razin (1995).

Using data on established Israelis and immigrants from the former Soviet Union of Israel, they estimate Mincer-type wage equations jointly for the two groups. They find that in the ten years following arrival, wages of highly skilled immigrants grow at 8 percent a year. Rising return to skills, occupational transitions, accumulated experience in Israel, and an economy-wide rise in wages account for 3.4, 1.1, 1.5, and 1.5 percent each. They do not reject the hypothesis that the return for experience converges to that of natives and that immigrants receive a higher return for their unmeasured skills. We find that there is some downgrading in the occupational distribution of immigrants relative to that of the established work force.

The second generation of Jews, whose parents immigrated from the former Soviet Union (FSU), experienced significantly higher upward mobility than all other ethnic groups. As documented by Aloni (2017), although the general association with parents' incomes within the FSU group is not very different compared to the population, their mobility relative to the national distribution is high, and the second generation finds its way even to the top percentiles. Table 3.1 shows the estimated probability of second generation outranking first generation in the full sample, and the groups' relative income rank convergence rates. Having higher probability to outrank parents highly depends on the relative income position of the group in the population's income distribution, thus, for example, Ethiopian and Arab children exhibit high upward mobility. However, controlling for their initial position, former Soviet Union (FSU) immigrants to Israel experienced the highest pace of upward mobility, while other groups converged to the mean slower.

4.1 Intergenerational Mobility

Table 4. Intergenerational Mobility Indicators by Israeli Ethnic Groups

	Israel	Asia / N. Africa	Euro. / America	FSU	Ethiopia	Arab
Probability of outranking parents	40%	49%	37%	58%	75%	59%
Rank shift pace, controlling for initial family position	-0.22 (0.17)	-0.02 (0.15)	- -	2.69*** (0.16)	-4.58*** (0.49)	-6.92*** (0.16)

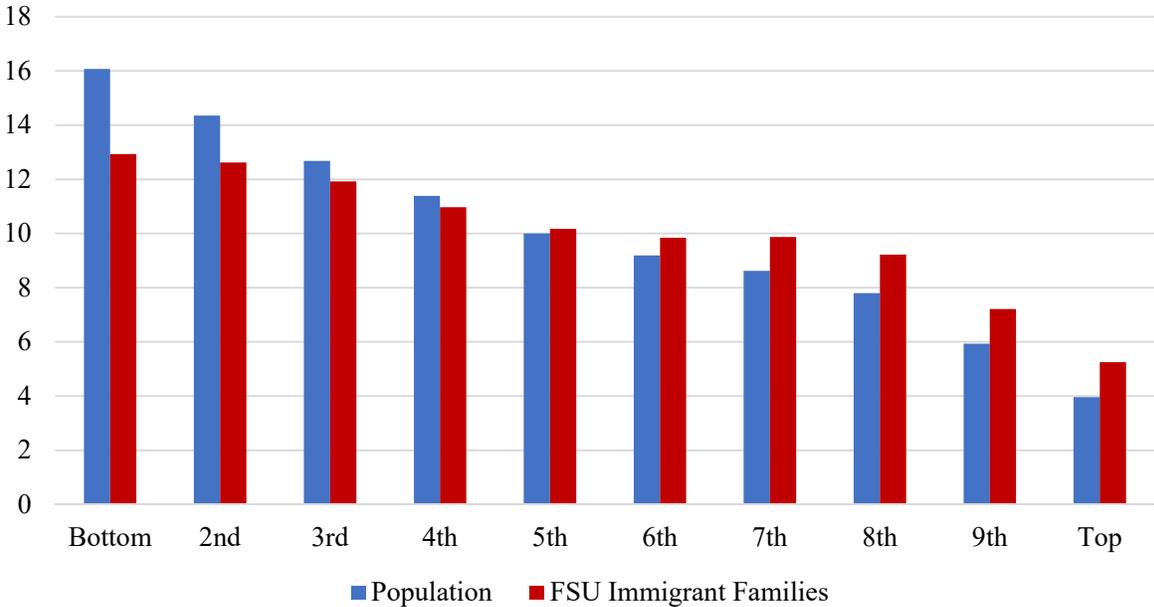

Notes: First row is the probability of the child of reaching higher percentile in children's generation distribution compared to parents' average percentile in their income distribution. Second row is the regression results of child-rank on the population groups' dummies, controlling for parents' income rank using 100 percentile dummies. Base group is of families with Asia / North Africa origins. The sample is of children born amongst 1979 to 1982 matched to parents using administrative data.

Standard errors in parentheses; upper asterisks indicate---*** $p < 0.01$,** $p < 0.05$,* $p < 0.1$.

Source: Aloni (2017).

Upward mobility is also indicated in Figure 2. The Figure shows the distribution of children of parents from the bottom decile. Comparing the FSU immigrants and the general population, the former experienced a greater upward mobility, with children reaching higher earning ranks, dispersing more evenly across the deciles.

Figure 2: Earning Deciles of Children Born to the Bottom-Decile Parents

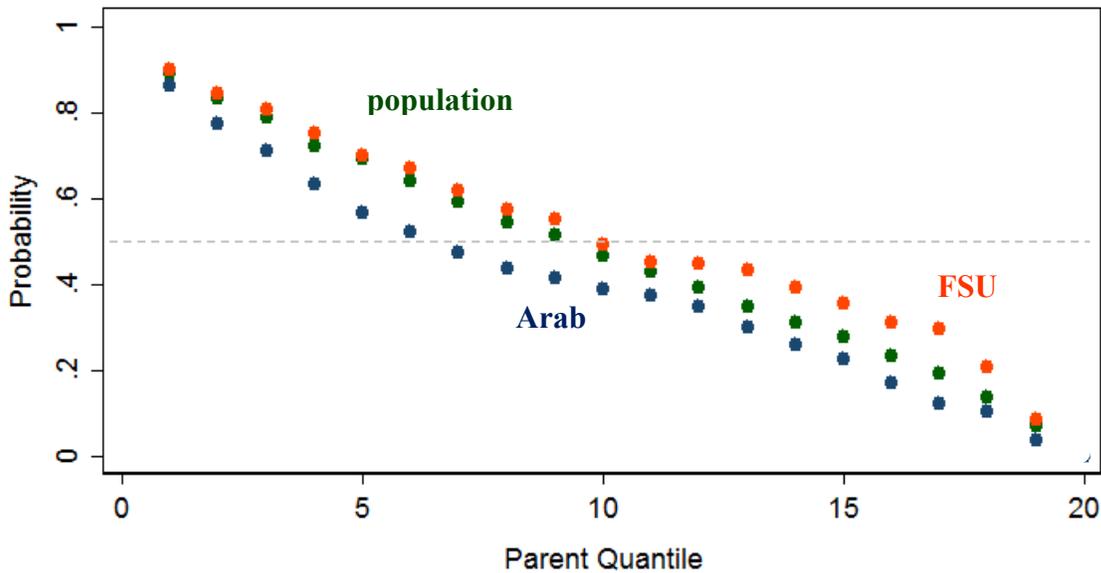

Source: Aloni (2017).

Figure 3 shows the probability of outranking parents by 5 percentiles, as a function of parents rank.

Comparing these two groups to the general population suggests an increasing polarization.

Figure 3: Probability of outranking parents by 5 percentiles by parents' quantiles

Note: Each point represents the proportion to have a children's rank higher than parents' do by at least 5 percentiles, binned on parents' quantile. Population excludes FSU and Arab population. The difference between FSU and Arab groups is significant in a 95% significance level throughout.

Source: Aloni (2017)

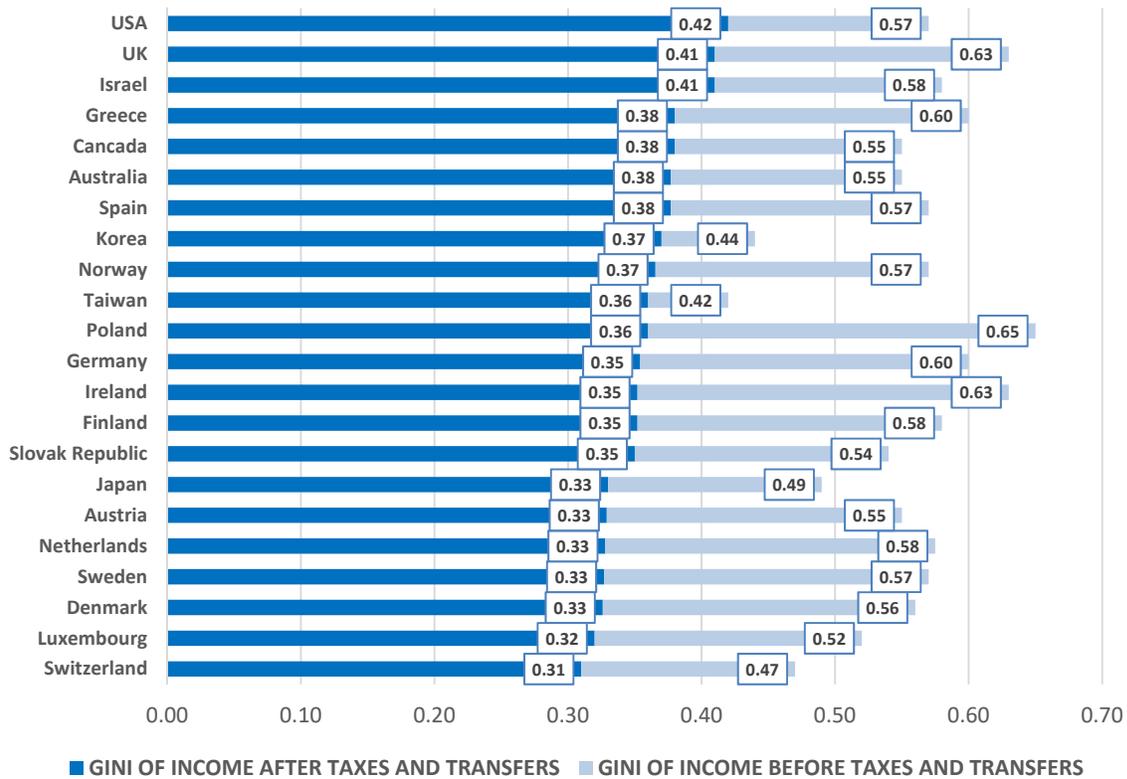

These documented facts that the FSU group has higher upward mobility, along with the fact that the Israeli-Arab group experienced slower upward mobility, may increase inequality. This is because the FSU first generation immigrants' income is high compared to the population, while Israeli-Arab families have a lower income mean.

4.2 Inequality

Israel's fast development, facilitated by the integration into the world economy, and the inflow of high skill immigrants, came at a cost of growing income inequality, measured by both as market-based and redistribution-based Gini coefficients. Currently, Israel, along with the US and UK are

at the top of market-forces generated inequality; and they do less than other OECD countries to reduce the inequality through the redistribution of income.¹³ See Figure 5.3.

Figure 4: Income Inequality and Redistribution

Source: Gornick and Jantti (2014).

¹³ See Gornick and Jantti (2014) for a comprehensive report on income inequality and redistribution among rich countries. Krugman (2006) argues that to the extent that globalization explains rising income inequality in the United States, it is through the effect of international trade on the “skill premium”, the gap between the incomes of college-educated workers and those without a college degree. What we know, however, is that rising inequality is not mainly about the rising skill premium. Only around a third of the rise in US inequality over the past generation is associated with a rising premium for education. Economic estimates indicate that the widening of the skill premium itself is more a result of “skill-biased technological change”, a growing demand for highly educated workers due to the rising importance of information technology, than a result of globalization.

To gauge the size of income redistribution one can subtract the market based Gini coefficient from the disposable income Gini coefficient. Israel's relatively high market-based inequality coefficient, shown in Figure 4, is driven by the large, and increasing, share of two relatively poor minority groups in the population: Ultra-orthodox Israeli Jews (primarily males), and the Israeli Arabs (primarily females¹⁴), stay out of the labor force. The rise in the share of these groups in the total population is because the fertility rates among these minorities are much higher than the other groups in the population¹⁵ In addition, the emergence of highly educated, economically active large group of Israelis, reinforced by the high skill immigration of Soviet Jews, made the upper tail of the distribution thicker. Israel is not an outlier in the OECD countries with respect to the market-driven (pre-tax-cum-transfer) income inequality. However, Figure 5 indicates the time dimension of inequality. Disposable-income inequality in Israel was roughly stable until the beginning of the 1990s, rose sharply thereafter, even though no such change occurs with respect to the market-generated inequality. Israel's level of redistribution of income falls short of many other OECD countries. A partial resolution of the issue, proposed by Razin, Sadka, and Swagel (2002), hinges on the political-economy effects of a rise in the dependency ratio. On the one hand, a higher dependency ratio means a larger pro-tax coalition, as the low income groups are net-beneficiary of the transfers from those who actively participate in the labor market. On the other, a higher

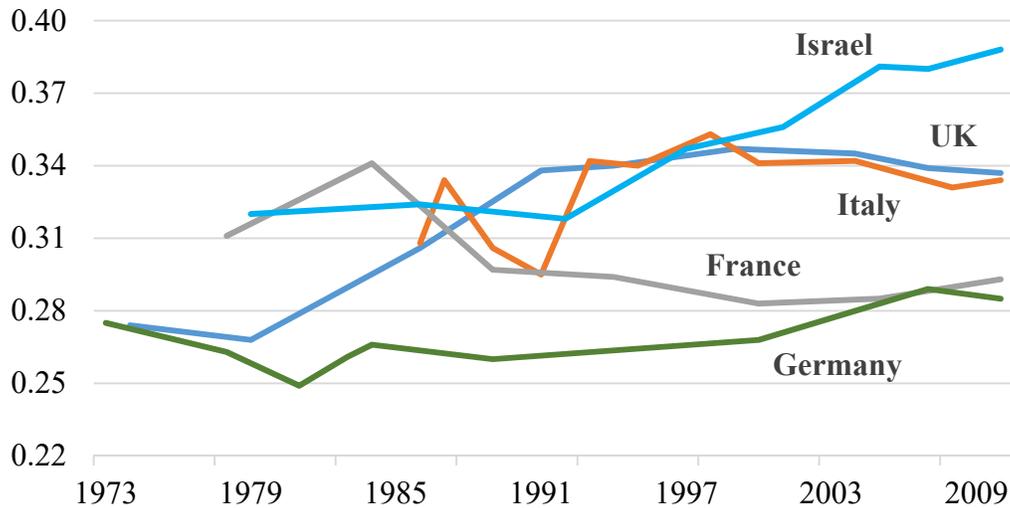

¹⁴ Yashiv and Kasir (2011) write: "The most prominent phenomenon among Arab women is the high level of variation in the rate of participation. Its source apparently lies in the differences between "modern" and "traditional" women from the point of view of education, family status, number of children and proficiency in various skills (such as knowledge of English and the use of a computer). There appears to be a dichotomy or some type of dual market, in which "traditional" women almost never participate. This can explain the low rate of participation in comparison to other countries. "Modern" women have quite a high rate of participation, which also explains the simultaneous increase in participation and levels of education over time, together with additional cultural changes. The finding that participation rates among Arab women are very different from those observed in Western countries and among Jewish women in Israel, though not significantly different from rates in Moslem countries".

¹⁵ Dahan (2007) explores the main factors behind the steep decline in the participation rate of Israeli men. He observes four factors responsible for the decline in participation rate between 1980 and 2001: increases in the population of students (21%), the ultra-Orthodox (21%), the disabled (32%), and discouraged workers (25%).

dependency ratio puts a higher tax burden on the people around the median voter, as it is necessary to finance transfers to a larger share of the population. People for whom the costs of higher taxes outweigh benefits shift to the anti-tax coalition. Hence, the second factor dominates in many of other rich countries. That is, the political-economy equilibrium-tax rate declines when the dependency ratio rises. This would be the case until society ages enough so that the median voter is retired, at which point there is a discontinuous jump up in the tax rate and corresponding increase in the share of transfers. In other words, the increased share of the fiscal net-beneficiaries in the population may have two opposing effects on redistribution policies. On the one hand, the political influence gained by low-income groups is persistently on the rise. This means that the median voter preferences shift over time in the direction of more generous welfare state.¹⁶ On the other hand, if the median voter, plausibly, does not belong the low-skill and non-working groups (as is probably also the case in Israel) then the increased share of the non-working and low-skill in the population may well lead policy-makers to lower taxes and transfers. Because, the increased fiscal burden which results for the large share of “net beneficiaries” adversely affect the median voter (she is a net contributor to the welfare system). The later affect dominates in Israel. Consequently, the entire redistribution system contracts.

¹⁶ About the voting right franchise in the US in the 1930s, Meltzer and Richard (1981) conclude: “In recent years, the proportion of voters receiving social security has increased, raising the number of voters favoring taxes on wage and salary income to finance redistribution. In our analysis the increase in social security recipients has an effect similar to an extension of the franchise.”

Figure 5: Disposable Income Inequality* in Israel and Several EU-15 Countries, 1973-2013

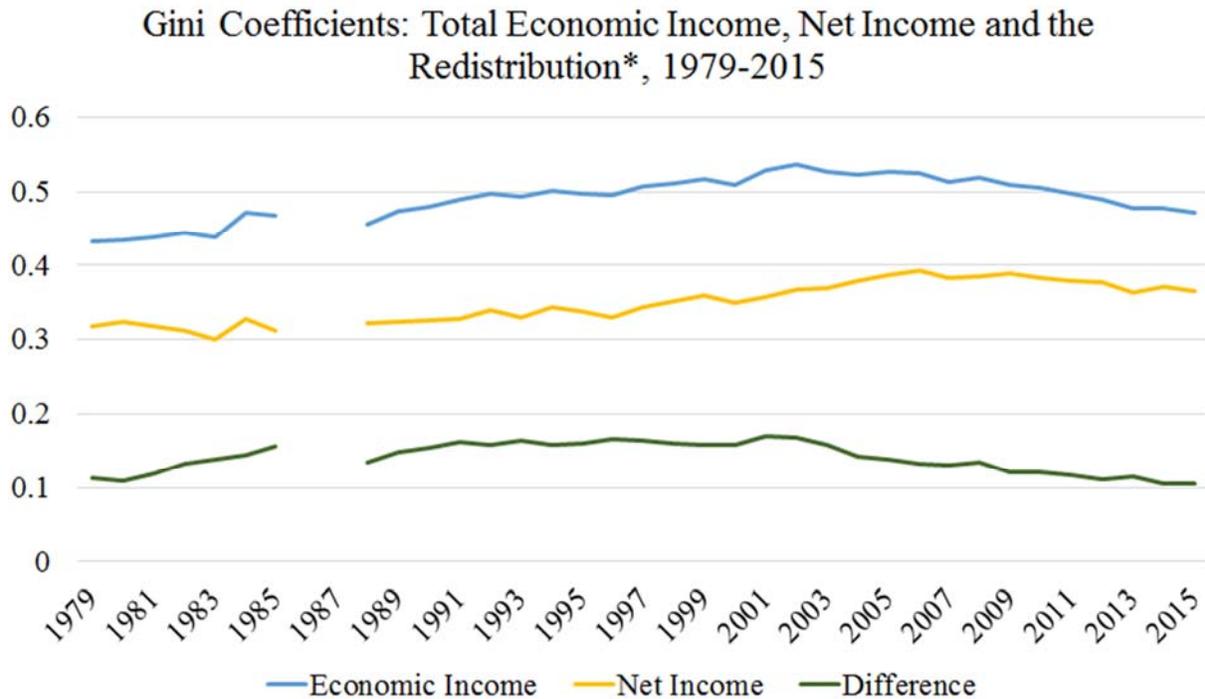

*Gini Coefficient

Source: Ben-David (2015)

Figure 6 demonstrates that redistribution Gini coefficient uptuned in 1989 and continues to rise until 2001. The implied more than a decade fall in income redistribution follows the Soviet-Jew immigration wave. The Figure demonstrates strong rise in income inequality between 1990 and 2003, which is a combination of declining market income inequality, more than offset by and a marked fall in redistribution. The influx of high skilled immigrants can explain these two conflicting trends: A rising middle class thanks to high- skill migration, and a rebalancing political-economy-based income redistribution policy.

Figure 6: Total Income, Net Income-Inequality and Redistribution 1979-2015

*The difference between total and net-income coefficients

Source: Dahan (2017)

Notes:

The years 99'-02' do not include East-Jerusalem population.

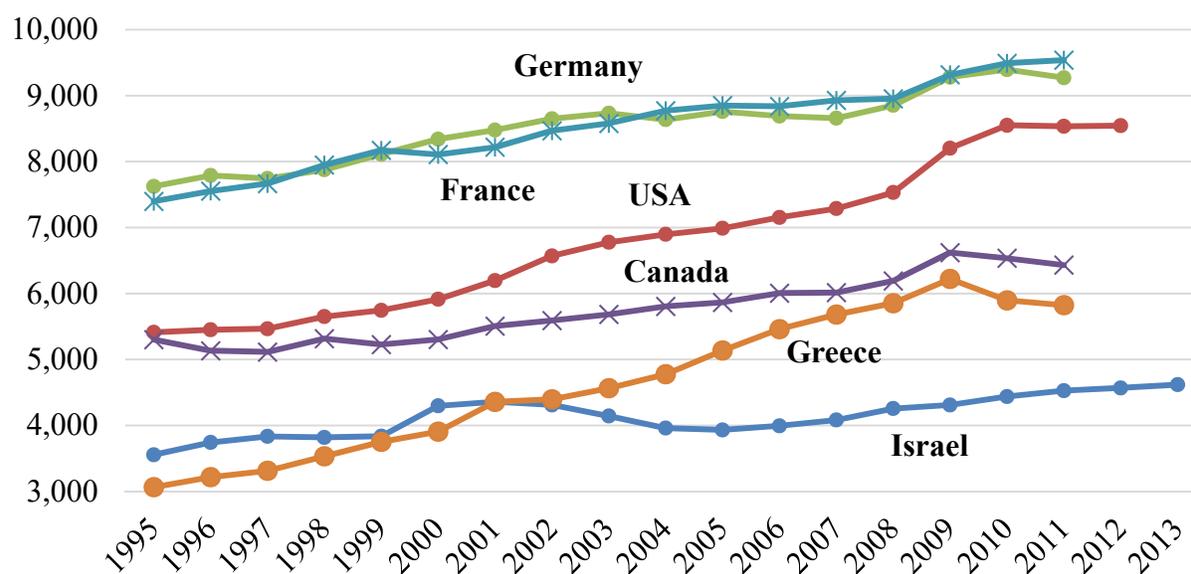

The years 12'-15' do not include the Bedouin population.

The unique position of Israel as a welfare state, among OECD countries, see Figure 5.6 highlights the low ranking of Israel in terms of its provision of social services per capita.¹⁷ High defense expenditures may have crowded out social services largely than in the other OECD countries. However, even though defense expenditures as a share of Israel GDP were following a distinct downward trend over the last 35 years, Israel diverges down in the provision of social expenditures,

¹⁷ Social expenditures temporarily increased during the migration wave, thanks to a one-shot absorption-type expenditure on new immigrants. They declined at the beginning of the 2000s.

relative to the OECD countries. Figure 7 plots the social expenditure, per capita, for Israel against selected group of countries. Israel is at the bottom of the group.¹⁸

Figure 7: Social Expenditures Per Capita, selected countries

Note: Constant 2005 PPPs, in US dollars

Source: OECD library.

¹⁸ A significant change in re-distribution over time is potentially related to a reduction in income taxes. Income Tax fell from 30 percent of revenues in 2000 to 20.4 percent in 2015. At the same time, VAT fell rose from 24.9 percent of tax revenues to 30.1 percent. Child allowances were severely cut. See also Bank of Israel (2014), and Strawczynski (forthcoming).

5. Immigrants and the Political System

Immigrants may also shift the balance of politics among ethnic groups, economic classes, or age groups, or may generate a massive political backlash. In Israel, the political backlash have been moderate, whereas the change in political balance was substantial. Israel's Law of Return grants returnees immediate citizenship and consequently voting rights. An early study by Avner (1975) finds that the voting turnout rate of new immigrants had been markedly lower than that of the established population. This means that immigrants did not fully exercise their voting rights and did not therefore influence the political economy equilibrium in Israel as much as the established population.

A similar migrant low voting turnout pattern is reported also by Messina (2007) and Bird (2011) for Western Europe. However, a later study about voting turnout pattern of new immigrants to Israel in the 2001 elections, conducted by Arian and Shamir (2002) reverse this finding for 2001. The new immigrants in this study are pre-dominantly from the FSU. Arian and Shamir (2002) find no marked difference in the voting turnout rates between these new immigrants and the established population. This is indeed a unique feature of the 1989-2001 immigration waves from the FSU. Relatedly,

Migration differs from the movement of other factor inputs (such as capital flows) in one fundamental way. Migrants become part of the society of the receiving country, including its evolving culture and politics. (The Swiss writer Max Frisch ironically declared: "We asked for workers. We got people instead.") In Highly developed social welfare, system in the receiving country may greatly complicate coalition-buildings political-economy matters, as emphasized by Razin, Sadka, and Suwankiri (2011). While high-skilled and therefore high-wage migrants may be

net contributors to the fiscal system, low-skilled migrants are likely to be net recipients, thereby imposing an indirect tax on the taxpayers of the destination country. Eventually, though, immigrants may shift the balance of politics among ethnic groups, economic classes, or age groups, or may generate a massive political backlash. Migrants may change the nature of social interactions, with shifts in religion, ethnicity, and cultural practices.

5.1 Political-Economy Theory¹⁹

To understand better the balance of the political-economic forces at play, one has to analyze the political-economy forces at play in a general-equilibrium setup. Razin and Sadka (2017) provide such a stylized general equilibrium model with free migration, where wages are endogenous and redistribution policy is determined by (endogenously determined) majority voting.²⁰ They address the issue of how migration can reshape the political balance of power, especially between skilled and unskilled and between native-born and migrants, and consequently to political-economic equilibrium redistribution policy of the welfare state. The general equilibrium model could provide insights as to how in a “natural experiment” manner, an external supply-side shock triggers a wave of skilled migration. The shock then can change wages, migration flows, and political coalitions, to reshape the political-economy balance and the redistributive policies.

5.1.1 Human Capital Investment

¹⁹ Based on Razin and Sadka (2017).

²⁰ The model is based on Razin, Sadka and Swagel (2002 a,b)

There are just two types of workers: “skilled” (with a symbol S) and “unskilled” (with the symbol U). The wage per unit of labor of a skilled worker is w , whereas an unskilled worker earns a wage of ρw per unit of labor, where $\rho < 1$,²¹ All native-born (N) are initially unskilled. However, a native-born can acquire education at some cost (c) and becomes skilled. Individuals differ from one another through their cost of education: there is a continuum of native-born individuals, distinguished only by their cost of education. For notational simplicity, we normalize the number of native-born individuals to one. An individual is identified by her cost of education, so that an individual with a cost of c is termed a c -individual. We assume for simplicity that the cost of education is uniformly distributed over the interval $[0, \bar{c}]$.

All native-born individuals are endowed with E units of a composite good, the single good in this economy. All individual in elastically supply one unit of labor. If a c -individual acquires education and becomes skilled, her income²² is denoted by I_S^N)

$$I_S^N(c) = (1 - t)w + b + (E - c)(1 + r)$$

, where t is a flat wage tax rate²³; b is a uniform (lump-sum) per capita social benefit; and r is the interest rate – the return to capital. If a c -individual decides not to acquire education and remain unskilled, her income (denoted by I_U^N) is

²¹ The model assumes that the only difference between skilled and unskilled labor is the efficiency units of labor each worker possesses. The simplifying assumption is made in order to focus on the political economy aspects of the analysis. There could be more tension between skilled and unskilled workers, such that the two types are complements (e.g., Doepke and Zilibotti (2005)). In this case, an increase in the supply of one type is beneficial to the other (e.g., migration of unskilled workers increases the marginal product of skilled workers). One can also assume that capital is more complementary to skilled worker than to unskilled (e.g., Krusell, Ohanian, Rios-Rull and Violante (2000)).

²² Note that this specification assumes that capital does not depreciate at all.

²³ In an unpublished version Razin and Sadka extended the tax to apply to capital income as well.

$$I_U^N = (1 - t)\rho w + b + E(1 + r) \quad (1)$$

(Note that $I_S^N(c)$ depends on c , whereas I_U^N does not)

Thus, there is a cutoff level of cost, c^* , so that all c -individuals with $c \leq c^*$ will choose to become skilled, and all the others (with $c \geq c^*$) will remain unskilled. This c^* is defined by

$$(1 - t)w + b + (E - c^*)(1 + r) = (1 - t)\rho w + b + E(1 + r).$$

Upon some re-arrangement, the cutoff level of the cost of education, c^* , becomes:

$$(1 - t)(1 - \rho)w = c^*(1 + r).$$

That is, c^* is solved from the equality between the return to education and its cost. A c^* -individual is just indifferent between acquiring education (and thereby becoming skilled) or staying unskilled. Upon further re-arrangement, c^* is defined by

$$c^* = \frac{(1-t)(1-\rho)w}{(1+r)}. \quad (2)$$

Note that c^* may well exceed E , which means that those c -individuals with c below but close to c^* (which is endogenous) actually borrow in order to acquire education. Naturally, the payoff in terms of the higher wage would more than offset the borrowing cost. For those individuals $E - c$ is negative.

Also, note that we are employing a static framework within which all economic and political processes occur simultaneously with no time dimension.²⁴ For instance, we do not

²⁴ Such a framework is akin to a steady state in a dynamic model with rational expectations.

distinguish between the time in which the education is acquired, and the time when the earnings occur. Similarly, capital earns its return r at the same time it is employed.

The number of c -individuals with $c \leq c^*$ is the number of native-born skilled individuals.

Denoting this number by n_S , it follows that

$$n_S = \frac{c^*}{\bar{c}}. \quad (3)$$

Then, the number of native-born unskilled individuals, n_U , is thus given by

$$n_U = 1 - n_S. \quad (4)$$

Aggregate investment in human capital (education), denoted by H , and is then given by

$$H = \int_0^{c^*} c \cdot \frac{1}{\bar{c}} dc = \frac{(c^*)^2}{2\bar{c}}. \quad (5)$$

Therefore, the aggregate stock of physical capital, K , is equal to²⁵

$$K = E - H. \quad (6)$$

There are also two types of migrants: the skilled who can earn a wage w in the host country, and the unskilled who earn a wage of ρw in the host country. None of them has any initial endowment. The migrants come to the host country after they have already made and implemented the decision whether to acquire or not acquire education. Thus, it is exogenously given who is skilled and who is unskilled. In other words, the economy benefits from the skilled migrants because it does not have to pay for the cost of investment.

²⁵ The reader will recognize the implicit assumption that the economy is not open to international trade. The effect of trade openness on inequality is therefore abstracted from the analysis.

7.2 Income Groups

The income of skilled and unskilled migrants, respectively, is:

$$I_S^M = (1 - t)w + b \quad (7)$$

, and

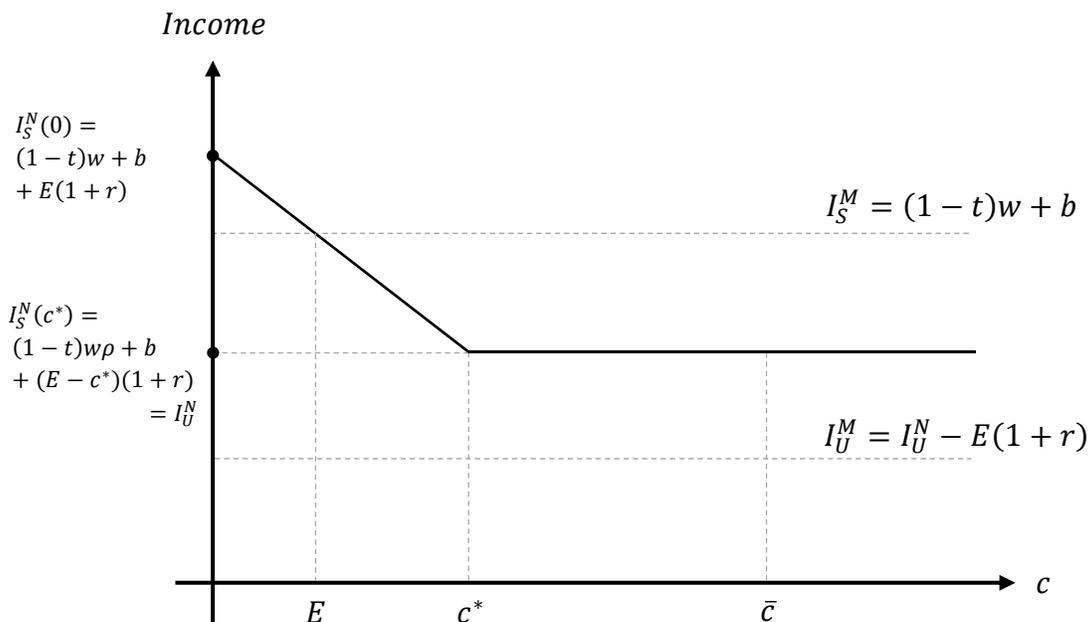

$$I_U^M = (1 - t)\rho w + b. \quad (8)$$

The income of the native-born as a function of c is depicted in Figure 3.4. Note that $I_S^N(c)$ declines in a straight line until it reaches c^* , where

$$I_S^N(c^*) = (1 - t)w + b + (E - c^*)(1 + r) = (1 - t)\rho w + b + E(1 + r) = I_U^N.$$

The labor income of the unskilled native-born and the unskilled migrants is the same, but the total income of an unskilled migrant which is $(1 - t)\rho w + b$ is definitely below the income of an unskilled native-born, the difference being the capital income enjoyed by the unskilled native-born, namely $E(1 + r)$. The total income of a skilled migrant is definitely higher than the total income of the unskilled migrant, because of the higher wage earned by the skilled, whereas both have no other income. The income of the skilled migrants exceeds the income of the skilled native-born with $c > E$, but falls short of the income of the skilled native-born with $c < E$.

Figure 8: Income Groups as function of Cost of Education

The income of a skilled migrant is $I_S^M = (1 - t)w + b$, whereas the income of a skilled c -individual is $(1 - t)w + b + (E - c)(1 + r)$. Therefore, as long as $E - c$ is positive (i.e. the c -individual does not borrow in order to invest in human capital), then $I_S^N(c) > I_S^M$. However, if $E - c < 0$ (i.e. the individual borrows in order to invest in human capital), then the income of the skilled migrant (I_S^M) is greater than the income of the skilled native-born (I_S^N). In sum, we have the following ranking of incomes:

$$I_U^M < I_U^N = I_S^N(c = c^*) < I_S^N(c > E) < I_S^N(c = E) = I_S^M < I_S^N(c < E).$$

5.1.2 Supply of Immigrants

Recall that the country employs an unrestricted migration policy. We envisage an economy that allows any migrants to come. Thus, the decision whether to immigrate or no rests solely with

the migrant. Each potential migrant has some reservation income, so that she will migrate if and only if she will be accorded a higher income in the destination country.

Due to various factors (such as skill, family ties, age, etc.) this reservation income is not the same, but there is rather a continuum of such reservation incomes. Distinguishing between the two skills groups, we then assume that there is an upward sloping supply function for each skill group, depending on the income accorded to immigrants in the destination country. Denoting the number of skilled migrants by m_S , the supply function of skilled migrants is given by an iso-elastic function:

$$m_S = B_S(I_S^M)^{\sigma_S} \quad (9)$$

, where B_S and σ_S are some positive parameters. Similarly, the supply function of unskilled migrants is given by

$$m_U = B_U(I_U^M)^{\sigma_U} \quad (10)$$

, where m_U is the number of unskilled migrants and B_U and σ_U are some positive parameters.

5.1.3 Production and Factor Prices

We employ a Cobb-Douglas production function

$$Y = AK^\alpha L^{1-\alpha}, A > 0, 0 < \alpha < 1 \quad (11)$$

, where Y is gross domestic product, A is a total factor productivity (TFP) parameter, and α is the capital-share parameter (and $(1 - \alpha)$ is the labor-share parameter). Symbol L indicates the total labor supply in efficiency units and is given by

$$L = n_S + \rho n_U + m_S + \rho m_U \quad (12)$$

The competitive wage per efficiency unit of labor (w) and the competitive interest rate (r) are given by the marginal productivity conditions

$$w = (1 - \alpha)A \left(\frac{K}{L}\right)^\alpha \quad (13)$$

, and

$$r = \alpha A \left(\frac{K}{L}\right)^{1-\alpha}, \quad (14)$$

, where we assume for simplicity that capital does not depreciate.

The model exhibits the standard gains from trade argument. (See appendix A, which remind us who are gainers and losers from the flow of skilled migrants).

5.1.4 Income - Redistribution System

We employ a very simple system of redistribution. Wages are taxed at a flat rate t . The revenues are distribution by a uniform per-capita transfer, b .

We assume that the migrants qualify for all the benefits of the welfare state, and they are naturally subject to the state taxes. Therefore, the government budget constraint is as follows:

$$twL = b(1 + m_S + m_U) \quad (15)$$

, assuming that the government has no other revenue needs, except for redistribution.²⁶

Note that it follows from equation (16) that t and b must be of the same sign. A positive wage tax (t) allows the government to accord a positive transfer (b) to all. A subsidy to wages (namely, a negative t) requires the government to impose a lump-sum tax (negative b) on all. When t and b are positive, the tax-transfer system is progressive. When they are negative, the system is regressive.

With unrestricted migration the flows of migrants m_S and m_U are determined by the migrants themselves according to their reservation incomes (embedded in the supply functions, (11) and (12)), and the income accorded to them in the host country. There are therefore only two policy variables – the tax rate, and the social benefit b . However, as the government is constrained by a balanced budget (condition (16)), it follows that there is essentially only one policy variables; once t is chosen, all the other economic variables are determined in equilibrium, including the tax revenue ($t w L$), the number of migrants (m_S , and m_U), and b . Alternatively, alternatively, once b is chosen, all the other economic variables are determined in equilibrium.

Choosing t as the single policy variable, we note that there remain 15 endogenous variables

$$w, b, r, c^*, I_S^M, I_U^M, n_S, n_U, I_S^N, m_S, m_U, H, K, Y, L.$$

There are also 15 equations in the model – (2)-(9) and (10)-(16) - from which the endogenous variables are to be solved²⁷.

²⁶ One may wonder why there is no tax on the initial endowment (E). In a distortive. However, in a dynamic setting which we mimic in a static framework, E represents accumulated savings, and taxing it will be distortive. Furthermore, because all native-born possess the same initial endowment, taxing it in our static model does not distribute income across native-born income groups; but taxing E amounts to transferring income from the native-born to the migrants static model such a tax is not.

²⁷ In addition, equation (1) defines I_S^N as a function of c .

The policy variable t is chosen by some natural and plausible version of a majority voting.²⁸

A two stage voting system is as follows. In the first stage the regressivity-progressivity of the system is determined. If the tax rate, t , and the social benefit, b , are both positive, the system is progressive. If the tax rate, t , and the social benefit, b , are both negative, the system is regressive. The system's progressivity is chosen by the *majority* of the voters.

In the second phase the magnitudes of the tax system, t , and b , are chosen by the *largest sub group* of the majority coalition.²⁹

Upon observation, we can see from equations (2) and (3) that the direct effect of the tax-transfer policy on the incomes of the unskilled native-born and the unskilled migrants is the same, and works through the net wage income $(1 - t)\rho w + b$. For the unskilled migrant this is the only effect of the tax-transfer system. However, for unskilled native-born, there is also an indirect effect through capital income $I(1 + r)$ (note that r depends on t); but this indirect effect is of a second-order magnitude compared to the direct effect.

Similarly, the direct effect of the tax-transfer policy on the incomes of the skilled native-born and the skilled migrants is the same and works through the net wage income $(1 - t)w + b$. Here again, there is also an indirect effect on the income of the skilled native-born (but not on the income of the skilled migrants) through the capital income $(E - c)(1 + r)$. Here again the indirect effect is of second-order magnitude.

²⁸ Since the composition of voters is endogenous, and the single-peak property of the voter preferences is not guaranteed, the median voter proposition is invalid.

²⁹ See also Lee et al (2004).

Thus, all unskilled (both native-born and migrants) are affected by the tax-transfer policy mainly through $(1 - t)\rho w + b$, whereas all skilled (both native-born and migrants) are affected mainly by $(1 - t)w + b$. It is therefore natural that all the unskilled whose wage is only ρw would rather prefer to tax wage income and take advantage of all the skilled whose wage is higher – w . Thus, the most preferred policy of the unskilled entails a positive tax and a positive transfer. Therefore, if the unskilled (both native-born and migrants) constitute a majority, then the political economy equilibrium tax and transfer will be positive – a progressive tax-transfer system. However, due to the indirect effect, which applies only to the unskilled native born, the most-preferred tax and transfer policy is not necessarily the same for the unskilled native-born and the unskilled migrants. We then postulate that when the unskilled form a majority, then the tax-transfer policy chosen is the most-preferred policy by the larger of the two sub-groups (the unskilled native-born or the unskilled migrants).

Similarly, the skilled (both native-born and migrants whose wage is higher than the unskilled) would opt to grant a subsidy to the wage, financed by a lump-sum tax. That is, they opt for negative t and b – a regressive tax-transfer policy. In this case too, there is also an indirect effect which applies only the skilled native-born. Thus, the most-preferred tax-transfer policy is not the same for the two sub-groups of skilled native-born and skilled migrants. In this case, too we postulate that the political-economy tax-transfer policy is the most-preferred policy of the larger sub-group.

Note that indirect effect of the tax-transfer policy, which works through the capital income, $(E - c)(1 + r)$ is not the same for all members of the skilled native-born sub-group (because it depends on c). In this case, we assume that the median voter within this group prevails.

If we keep all other parameter values constant and increase only the parameter value of B_S , we can isolate the effect of a supply side shock. That is, we give a positive shock to the supply of skilled migrants. We find that number of skilled migrants (m_S) rises sharply. The skilled constitute now the majority $x_S + m_S > x_U + m_U$. As predicted, the political-economy tax-transfer policy becomes now regressive: t and b are negative. That is, there is a wage subsidy financed by a lump sum tax. In addition, the skilled migrants form the larger of the two skilled sub-groups, (i.e. $m_S > x_S$) and their most-preferred tax-transfer policy becomes now the political-equilibrium tax-transfer policy. Furthermore, the politically dominant sub-group of skilled migrants drives out all unskilled migrants ($m_U = 0$), by according them zero disposable income ($I_U^M = 0$).

Noteworthy, the unskilled native-born were initially the politically dominant sub-group and dictated their most-preferred progressive tax-transfer. Following the supply-side stock of skilled migration, the unskilled native-born lose their dominance to the skilled migrants who are now dictating their most-preferred regressive tax-transfer policy. Nevertheless, the unskilled native-born are better off, because the return to their capital income (namely, r) rises sharply (in unit of the all-purpose composite good). Even though the wage per efficiency unit falls, the sharp rise in the rate of interest (from 1.55 to 2.94) more than compensates the native-born unskilled for the wage decline. For the same reason, the skilled (native-born and migrants) are all better off. Thus, except for the unskilled migrants, who are driven out, all other income groups gain from the skilled-migration supply shock.

Note that the influx of skilled labor raises overall productivity of the labor force; consequently, it does also raise the tax revenue needed for shouldering the pre-existing redistribution policy. This force works towards more generous-redistribution, because it is fiscally less burdensome. Counteracting this pro-distribution force, however, is the rebalancing of the political coalition

triggered by the increased share of higher-income skilled in the voting population. The result is that the emerging decisive voter *reverses* the pre-existing redistribution regime.³⁰

It is worth explaining the model specific forces that totally drive out the unskilled migrants in the wake of the skilled-migration supply shock. The model assumes perfect substitutability between skilled and unskilled labor in production: each unit of time of an unskilled worker is equivalent to ρ units of time of a skilled worker. Thus, unskilled migrants provide no productivity benefits to the skilled. At the same time, they constitute a fiscal burden. Therefore, the new skilled-dominant coalition drive them out altogether by pushing their disposable income all the way to zero. The assumed perfect substitutability in production does serve to highlight the anti-unskilled-migration forces within the ruling skilled coalition. The perfect labor substitutability assumption overstates market-based inequality in the model. If the supply elasticity of skill migrant is larger than that of unskilled, it will reinforce the flows of skilled and the outflows of unskilled because of the migration shock. In a steady state of standard dynamic models, in general, there is more labor substitutability than in that during the transition- dynamic state. This provide plausibility to our perfect substitutability assumption. If one introduces into the analysis Heckscher-Ohlin elements of the traded-non traded sectoral structure, it will serve in our model to understate market based income inequality in our one-sector model. Because these elements tend to mitigate the wage decline following the migration shock.³¹

6. The migration-inequality model's predictions

³⁰ For numerical simulation, see appendix B.

³¹ See Burstein et al (2017).

The model attempt to rationalize the sharp rise in income inequality following the Soviet-Jew Exodus shock, based on unusual electoral participation by the new immigrants. It allows us to explore how migration supply side shock alters immigration patterns and, at the same time, reshapes the political-economy balance we develop a stylized political-economy model with free migration. Important political-economy mechanisms are at work: First, the influx of skill-immigrants depresses the incentives for unskilled migrants to flow in, though they are still free to do so. Second, the fiscal burden of redistribution policies diminishes from the viewpoint of the decisive voter. That is, the influx of skilled labor raises overall productivity of the labor force; consequently, it also raises the tax revenue needed for shouldering a redistribution policy. However, counteracting this pro-distribution force is the rebalancing of the political coalition, because the share of the increase in the skilled in the population. Therefore, the emerging decisive voter reverses pre-existing the redistribution regime, notwithstanding the fall in the fiscal burden. Third, nonetheless, the unskilled native-born may well become well off, even though they lose their political influence. To sum up, the model prediction are as follows. First, the shock depresses the incentives for unskilled migrants to flow in, though they are still free to do so. Second, tax-transfer system becomes less progressive. Third, the unskilled native-born may well become well off, though they lose their political influence, which they had before the migration wave. All other native-born income groups are also made better off. The positive economics predictions seem to be consistent with data. Theory is motivated by the unique migration experience of Israel of a supply-side shock triggering skilled immigration and the concurrent decline in welfare-state redistribution. This paper develops a model, which can provide an explanation for the mechanism through which a supply-side shock triggering high-skill migration can also reshape the political-

economy balance and the redistributive policies. The paper highlights the differences in the political-economy induced redistribution policies between the cases in which migrants participate in the electoral system and the case where they do not. When migrants are allowed to vote, and they take advantage of this right, then, following the shock, all income groups gain, except low skilled immigrants who lose. When migrants are not allowed to vote, or choose not to participate in elections, all income groups gain, except the skilled migrants who lose.

7. Conclusion

The paper describes a unique experience of Israel. Within a short time period in the early 1990s, Israel received scores of migrants from the Former Soviet Union (FSU). Its distinctive feature was the migrants' high labor skill. Following the immigration wave, the political-economy balance shifted towards a government pursuit of more regressive policy. Such a significant change in re-distribution over time is underpinned by a secular reduction in income taxes. Income Tax fell from 30 percent of revenues in 2000 to 20.4 percent in 2015. At the same time, VAT fell rose from 24.9 percent of tax revenues to 30.1 percent. It caused a sharp new upward trend of disposable income inequality but without a parallel change in market income inequality. That is, the welfare state took a sharp regressive turn. The model developed in the paper helps explain what is shown Figure 6: a moderate rise in net income inequality after 2000, which is a combination of declining market income inequality, and an offsetting fall in income redistribution. The influx of high skilled immigrants can explain both: A rising middle class and a rebalanced political economy equilibrium.

This underscores the role played by the post migration political balance, which triggered less redistribution.

Appendix A: Gains to Native-born from Migration

Like international trade in goods, there are gains and losses from the opening of national borders to labor mobility. A simple figure (Figure A) can serve to illustrate the gains from migration in our model. For concreteness, we illustrate the gains to the native-born from low-skilled migration. For simplicity, we assume that there are no taxes and benefits.

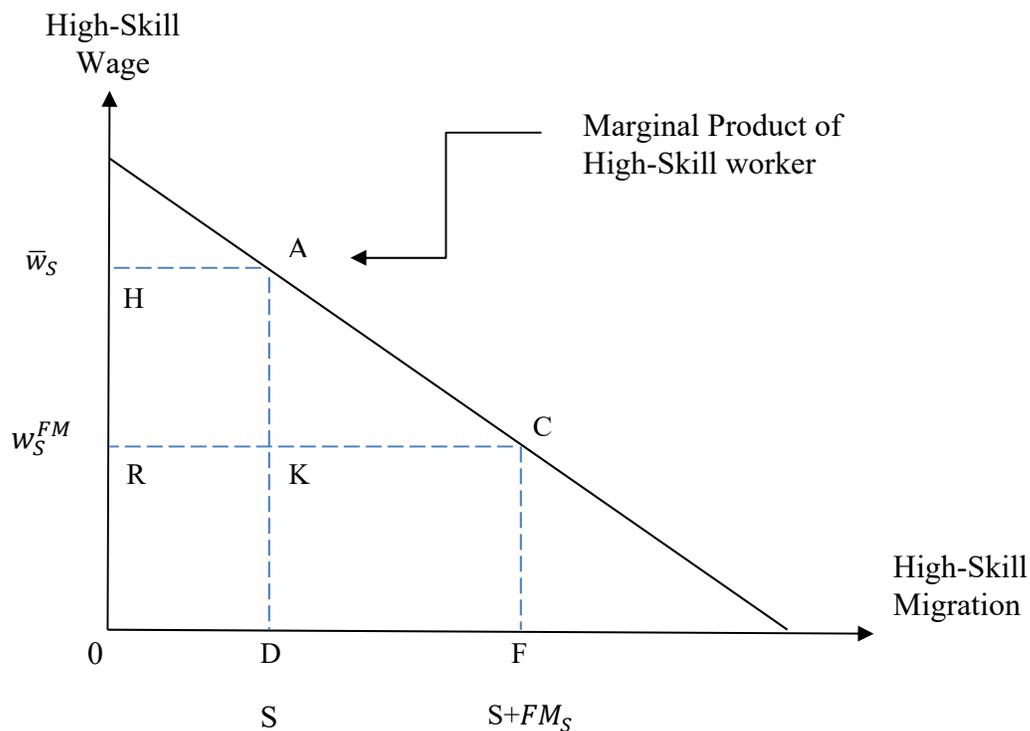

The down slopping curve in this figure is the marginal product of low-skilled labor. This curve is also the demand for this type of labor.

There are S native-born high-skill labor. Free-migration number of high skilled immigrants is FM_S .

In a closed economy with no migration, the equilibrium high-skilled wage is w_S .

GDP is equal to the area OGAD, of which the area HGA goes to the high-skill native-born and the area OHAD goes to the low-skill native-born.

Figure A: The Gains from a High -Skill Migration

Suppose the high-skill migrants face a reservation wage of w_S^{FM} in their countries of origin, which is below the threshold \bar{w}_S . If we allow for a free migration then FM_S high-skilled migrants will come. The equilibrium wage will be: w_S^{FM} . GDP increases to OGCF (to both native-born and migrants).

An increase measured by the area DACF.

A part of this increase (the area DKCF) goes to the low-skilled migrants, so that the total gains to all the native-born is the area AKC. Note, however, that not all native-born gain. The income of High -skill native-born drops to the area ORKD, so that they lose the area HAKR. On the other hand, the income of the high-skill native-born exceeds the loss to the low-skill native-born.

Therefore, with a perfect, non-distortionary system of redistribution (via lump sums), the high-skilled native-born can more than compensate the low-skilled native-born, so that all native-born can gain from migration.

Note also that if the migration of high skill trigger either productivity gains (through external effects) or an increase in infrastructure investment (through policy effects) the marginal productivity curve would shift outwardly. Therefore, the wage of high skill under free migration need not fall.

Because a redistribution system (via wage taxation) is distortionary, the compensation possibilities are limited. It is not always the case that all native-born gain from migration. A similar conclusion holds in the case of high-skilled migration.

A striking result in Chapter 2 is that the migration supply shock benefit all income groups despite of the distortionary redistribution system and driven by political-economy forces.

Appendix B: Migrant's Votes vs. Migrant's does Not Vote

The migration-inequality model, motivated by the Israeli experience with the wave of skilled migration from the FSU, simulates the effects of a supply shock of skilled migration on the political economy equilibrium tax-transfer policy. To highlight the role of electoral participation by immigrants, we compare two political regimes. In the first one migrants do not vote. In the second, migrants vote.

We start with parameter values that entail the unskilled (both native-born and migrants) as a majority. This case is described Figure B (a) and (b). As predicted, the political-economy tax-transfer policy is progressive: t and b are positive. Also, the unskilled native-born form a majority of the unskilled. We then contemplate a skilled migration supply shock that is we keep all other parameter values constant and increase the skilled migration parameter value. Following the supply-side shock of

skilled migration, in part (a), the unskilled native-born do not lose their political dominance to the skilled migrants. Their most-preferred progressive tax-transfer policy is unchanged. Nevertheless, the unskilled native-born are better off, because the return to their capital income (namely, r) rises.

Following the supply-side shock of skilled migration, in part (b), the unskilled native-born lose their dominance to the skilled migrants who are now dictating their most-preferred regressive tax-transfer policy.

Nevertheless, the unskilled native-born are better off, because the return to their capital income

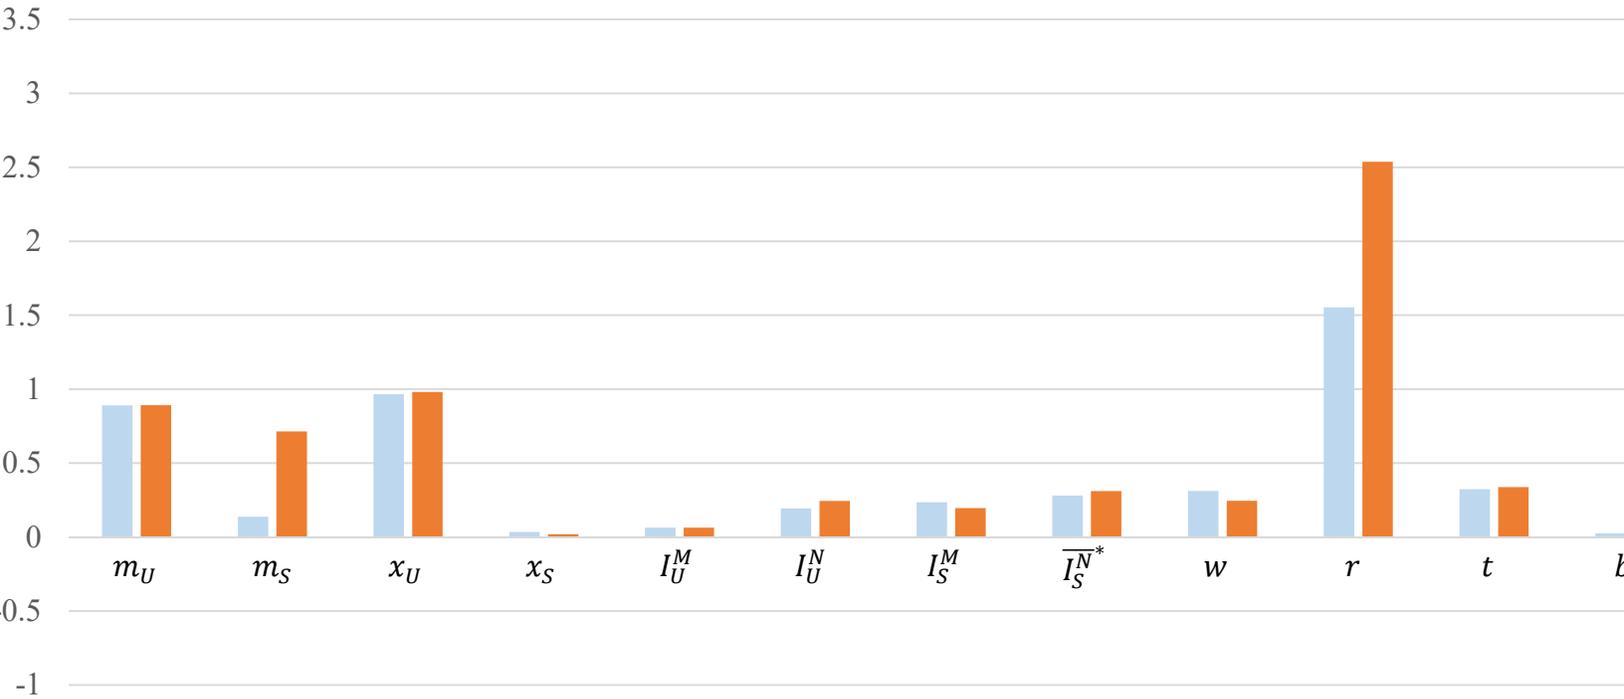

Rises .See Figure B (a), (b).

The comparison between the two cases is insightful. When not given the right to vote, the supply-side shock of skilled migration (case (a)) renders the fiscal system more progressive. By contrast, when the migrants have the right to vote (which they fully exercise), they cause the fiscal system to be regressive. Noteworthy, when they are not allowed to vote, the skilled migrants lose and all other income groups gain. When they are allowed to vote it is the unskilled migrants who lose, and all other income groups gain.

The model therefore help explain what is shown Figure 1 for the Israeli episode: a rise in income inequality between 1990 and 2003, which is a combination of declining market income inequality and a more than offsetting fall in redistribution. The influx of high skilled immigrants can explain both: A rising middle class and a rebalanced political economy based income redistribution policy.

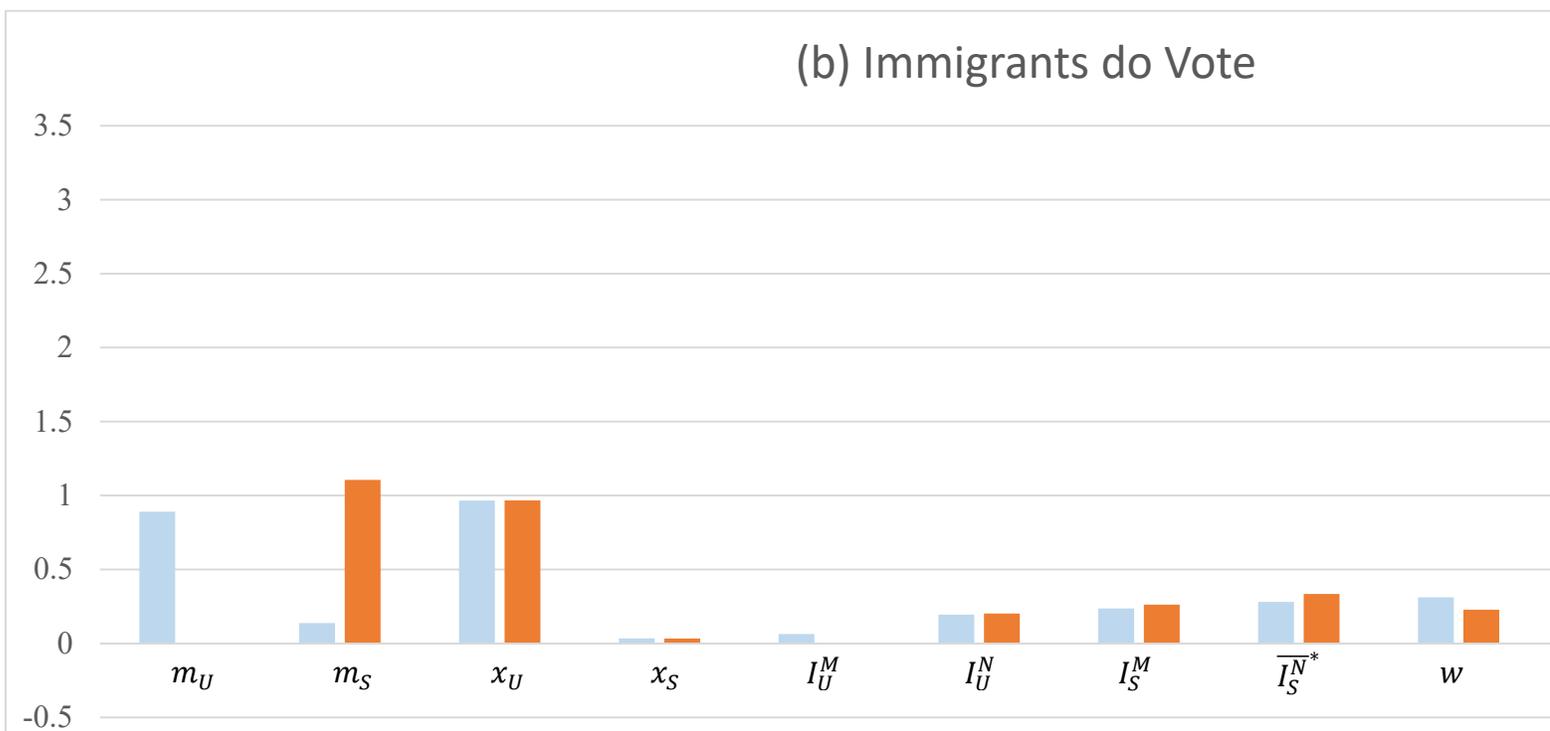

Figure B: The Effect of a Supply Shock of Skilled Migration

(a) Immigrants do not Vote

■ Unskilled Majority (Unskilled Native-Born the Larger Group) - Parameter Value of $B_s = 1.2$
■ Unskilled Majority (Unskilled Native-Born the Larger Group) - Parameter Value of $B_s = 8.2$

(b) Immigrants do Vote

Notation:

$w = \text{wage}$, $r = \text{return}$, $I_S^M = \text{skilled - migrant - income}$, $I_U^M = \text{unskilled - migrant - income}$, $n_S = \text{skilled native numbers}$, $n_U = \text{unskilled native numbers}$, $I_U^N = \text{unskilled native income}$, $I_S^N = \text{skilled native income}$, $m_S = \text{skilled migrant's numbers}$, $m_U = \text{unskilled migrant's numbers}$, $t = \text{tax rate}$, $b = \text{social benefit}$.
